Motivations

- Existence of DM established from astro/cosmo observations

- DM-DM, DM-SM force carried by some mediators

- Dark photon : the most common. Usually the origin of its mass is ignored (assuming Stueckelberg mechanism)

- Dark Higgs : a kind of the must for massive dark photon within perturbation ⟶ Main theme of this talk

Summary

- Phenomenology of HP VDM and Singlet FDM presented within EFT vs. UV completed models

- EFT approach has a number of drawbacks : non-renormalizable, unitarity violation at high energy colliders, and it applies only if $m_{DM}, m_{\mathrm{SM}} \ll m_\phi$ [But we don't know mass scales of dark particles !]

- In particular, one has $\Gamma_{\mathrm{EFT}}(H_{125} \to VV) \to \infty$, as $m_V \to 0$, whereas it is finite in UV completed models [Importance of gauge invariance, unitarity and renormalizability]

- The dark Higgs ϕ can play crucial roles in interpreting the DM signatures at colliders, explaining the GC γ-ray excess ($VV \to \phi\phi$), improving vacuum stability up to Planck scale, modifying the Higgs inflation [ϕ should be actively searched for !]

Inelastic DM and XENON1T Excess

We consider Both Scalar and Fermion IDM

XENON1T Excess

- Excess between 1-7 keV

  - Expectated : 232 ± 15 , Observed : 285

  - Deviation ~ 3.5 σ

- Tritium contamination

  - Long half lifetime (12.3 years)

  - Abundant in atmosphere and cosmogenically produced in Xenon

- Solar axion

  - Produced in the Sun

  - Favored over bkgd @ 3.5 σ

- Neutrino magnetic dipole moment

  - Favored @ 3.2 σ

Electron recoil
DD/CMB Constraints

- To evade stringent bounds from direct detection expt's : sub GeV DM

- CMB bound excludes thermal DM freeze-out determined by S-wave annihilation : DM annihiliation should be mainly in P-wave $\langle \sigma v \rangle \sim a + bv^2$

Planck 2018

Exothermic DM

- Inelastic exothermic scattering of XDM

- $XDM + e_{\text{atomic}} \rightarrow DM + e_{\text{free}}$ by dark photon exchange + kinetic mixing

- Excess is determined by $E_R \sim \delta = m_{XDM} - m_{DM}$

- Most works are based on effective/toy models where δ is put in by hand, or ignored dark Higgs

- dim-2 op for scalar DM and dim-3 op for fermion DM : soft and explicit breaking of local gauge symmetry, and include massive dark photon as well $\rightarrow$ theoretically inconsistent !

Z$_2$ DM models with dark Higgs

- We solve this inconsistency and unitarity issue with Krauss-Wilczek mechanism

- By introducing a dark Higgs, we have many advantages:

  - Dark photon gets massive

  - Mass gap δ is generated by dark Higgs mechanism

  - We can have DM pair annihilation in P-wave involving dark Higgs in the final states, unlike in other works

Usual Approaches

$$V(\phi) = m^2|\phi|^2 + \Delta^2\left(\phi^2 + \phi^{*2}\right), \qquad (1)$$

This term is problematic

$$\mathcal{L} = g_D A'^{\mu}\left(\chi_1 \partial_\mu \chi_2 - \chi_2 \partial_\mu \chi_1\right) + \epsilon e A'_\mu J^\mu_{\text{EM}},$$

Similarly for the fermion DM case
FIG. 1. Inelastic scattering of the heavier DM particle χ_2 off the electron e into the lighter particle χ_1, mediated by the dark photon A'.

- The model is not mathematically consistent, since there is no conserved current a dark photon can couple to in the massless limit

- The second term with Δ^2 breaks $U(1)_X$ explicitly, although softly

FIG. 4. The required value of ϵ to explain the observed excess of events at XENON1T in terms of the dark photon mass $m_{A'}$ (black solid lines). The left and right panels correspond to the cases of $m > m_{A'}/2$ and $m < m_{A'}/2$ respectively. We assume $g_D = 1.2$ in both cases. The blue lines denote the required value of ϵ to obtain the observed DM abundance by the thermal freeze-out process, discussed in Sec. IV. The solid lines correspond to the case without any entropy production. The dashed lines assume freeze-out during a matter dominated era and the subsequent reheating at $T_{\rm RH}$, which suppresses the DM abundance by a factor of $(T_{\rm RH}/T_{\rm FO})^3$. The black dashed lines denote the mass density of χ_2 normalized by the total DM density. The shaded regions show the constraints from dark radiation and various searches for the dark photon A' which are discussed in Sec. V.

Without dark Higgs, one can not consider light FDM, because of CMB bounds on the S-wave annihilation

Summary

- Local Z2 scalar/fermion DM : theoretically well defined & mathematically consistent models for XDM

- Can explain a number of phenomena including the recent XENON1T data

- One can discriminate the spin of (X)DM at Belle2 from the polar angle distributions of the decaying points

- DM mass and the Δm can be determined with the focus point method

- Similar studies at ILC, CEPC, HL-LHC and FCC-hh in progress (The current version of FCC CDR does not include this interesting case.)

Z' Only

- Consider light Z' and $g_X \sim (\text{a few}) \times 10^{-4}$ for the muon g-2. Then

- $\chi\bar{\chi} \to Z'^* \to f_{\mathrm{SM}}\bar{f}_{\mathrm{SM}}$: dominant annihilation channel

- $g_X \sim 10^{-4}$ is too small for $\chi\bar{\chi} \to Z'Z'$ to be effective for $\Omega_\chi h^2$

- $m_{Z'} \sim 2m_{\mathrm{DM}}$ with the s-channel Z' resonance for the correct relic density

- Many recent studies on this case:

- Physics depends on Q_Φ , Q_X and Q_χ

- $Q_\Phi = 2Q_{X(\chi)}$ and $3Q_X$ need special cares, since there are extra gauge invariant op's that break $U(1) \rightarrow Z_2$, Z_3 after $U(1)$ is spontaneously broken by nonzero VEV of Φ

Conclusion

- DM physics with massive dark photon can not be complete without including dark gauge symmetry breaking mechanism, e.g. dark Higgs field ϕ, which have been largely ignored by DM community (or some ways other than dark Higgs to provide dark photon mass)

- Many examples show the importance of ϕ in DM phenomenology, astroparticle physics and cosmology

- Once ϕ is included, can accommodate the muon g-2 and thermal DM without the s-channel resonance condition $m_{Z'} \sim 2m_{\mathrm{DM}}$

- m_{DM} : essentially free, whereas $m_{Z'} \sim O(10-100)$ MeV and $g_X \sim O(10^{-4})$ can explain the muon (g-2)

Higgs-Portal Assisted Higgs Inflation

With Jinsu Kim, Wan-Il Park

Higgs Inflation

- Inflation : the main paradigm for very early Universe

- But no very compelling inflation scenarios based on high energy physics

- SM Higgs boson can play a role of inflaton if it has large non minimal coupling [Bezrukov, Shaposhnikov (2007)] or non canonical kinetic term

- Merits: Minimal model, Consistent with Planck data, Can connect low energy (m_{EW}) scale to high energy (inflation) scale

Higgs Inflation in SM

$$\frac{\mathcal{L}}{\sqrt{-g}} = -\frac{1}{2\kappa}\left(1 - \xi\frac{h^2}{M_{\text{Pl}}^2}\right)R + \mathcal{L}_h$$

Nonminimal coupling

$$\epsilon = \frac{M_P^2}{2}\left(\frac{dU/d\chi}{U}\right)^2 \simeq \frac{4M_P^4}{3\xi^2 h^4}$$

$$U(\chi) = \frac{1}{\Omega(\chi)^4}\frac{\lambda}{4}(h(\chi)^2 - v^2)^2$$

$$\eta = M_P^2 \frac{d^2U/d\chi^2}{U} \simeq -\frac{4M_P^2}{3\xi h^2},$$

$$\Rightarrow \epsilon \simeq \frac{3}{4}\eta^2$$

$$n_s = 1 - 6\epsilon + 2\eta \sim 0.96$$

$$\Rightarrow \eta \simeq \frac{1}{2}(n_s - 1)$$

$$\Rightarrow \epsilon \simeq \frac{3}{16}(n_s - 1)^2$$

Here $\xi_s = 0$, $\lambda_{SH} = 0.1$, $\lambda_S = 0.2$, and $\lambda_\psi = 0.3$ at M_t scale are used. The nonminimal coupling of the SM Higgs to gravity, ξ_h, is chosen in such a way that the Planck normalization (3.8) is satisfied. The grey-dotted lines indicate the parameter region where the spectral index n_s becomes larger than 2σ Planck bound, $n_s \gtrsim 0.98$. Similar behaviors are found for different sets of model parameters.

The stringent upper bounds for a given m_s comes from the DM physics. The values of the other parameters are the same as in figure 4. Color-shaded regions (following the scheme of colored lines) are the excluded regions from the latest LUX experiment, corresponding to different dark Higgs masses.

Large $r \sim O(0.1)$ is possible in HP assisted HI, without tight connection to m_t, m_h

Summary

Message to take home

- DM interacting with massive dark photon is a typical scenario in DM physics

- Very often, dark Higgs boson (or some mechanism to generate dark photon mass) has been ignored

- However, there are many examples that show importance of dark Higgs boson

- In this talk, I discussed the following examples:

- HP VDM: $\Gamma_{\mathrm{inv}}(H \to VV)$ and GC γ-ray excess

- XENON1T excess in terms of exothermic scattering of inelastic DM (both scalar and fermion DM)

- $U(1)_{L_\mu - L_\tau}$-charged scalar/fermion DM outside the $m_{Z'} \sim 2m_{\mathrm{DM}}$ window

- Higgs-portal assisted Higgs inflation with large $r \sim O(0.1)$

- Additional dark Higgs (singlet-like scalar) : generic (in DM models with dark gauge symmetry), improves EW vac stability >> should be actively search for @ LHC and other future colliders

DM is stable because...

- ## Symmetries
  - (ad hoc) Z_2 symmetry, etc
  - R-parity
  - Topology (from a broken sym.)

- ## Very small mass and weak coupling

  e.g: QCD-axion ($m_a \sim \Lambda_{QCD}^2/f_a$; $f_a \sim 10^{9\text{-}12}$ GeV)

  $$\Gamma_a \sim \mathcal{O}(10^{-5}) \frac{m_a^3}{f_a^2} \ll H_0 \sim 10^{-42} \text{GeV}$$

But for WIMP ...

- Global symmetry is not enough since

$$-\mathcal{L}_{\mathrm{int}} = \begin{cases} \lambda \frac{\phi}{M_{\mathrm{P}}} F_{\mu\nu} F{\mu\nu} & \text{for boson} \\ \lambda \frac{1}{M_{\mathrm{P}}} \bar{\psi} \gamma^\mu D_\mu \ell_{Li} H^\dagger & \text{for fermion} \end{cases}$$

Observation requires [M.Ackermann et al. (LAT Collaboration), PRD 86, 022002 (2012)]

$$\tau_{\mathrm{DM}} \gtrsim 10^{26-30} \sec \Rightarrow \begin{cases} m_\phi \lesssim \mathcal{O}(10)\mathrm{keV} \\ m_\psi \lesssim \mathcal{O}(1)\mathrm{GeV} \end{cases}$$

⇒ WIMP is unlikely to be stable

- SM is guided by gauge principle

It looks natural and may need to consider a gauge symmetry in dark sector, too.

Why Dark Gauge Symmetry ?

- Is DM absolutely stable or very long lived ?

- If DM is absolutely stable, one can assume it carries a new conserved dark charge, associated with unbroken dark gauge sym

- DM can be long lived (lower bound on DM lifetime is much weaker than that on proton lifetime) if dark sym is spontaneously broken

Higgs can be harmful to weak scale DM stability

Z2 sym Scalar DM

$$\mathcal{L} = \frac{1}{2}\partial_\mu S \partial^\mu S - \frac{1}{2}m_S^2 S^2 - \frac{\lambda_S}{4!}S^4 - \frac{\lambda_{SH}}{2}S^2 H^\dagger H.$$

- Very popular alternative to SUSY LSP

- Simplest in terms of the # of new dof's

- But, where does this Z2 symmetry come from ?

- Is it Global or Local ?

Fate of CDM with Z2 sym

- Global Z2 cannot save DM from decay with long enough lifetime

Consider Z_2 breaking operators such as

$$\frac{1}{M_{\text{Planck}}} SO_{\text{SM}}$$

keeping dim-4 SM operators only

The lifetime of the Z_2 symmetric scalar CDM S is roughly given by

$$\Gamma(S) \sim \frac{m_S{}^3}{M_{\text{Planck}}^2} \sim (\frac{m_S}{100\text{GeV}})^3 10^{-37} GeV$$
The lifetime is too short for ~100 GeV DM

Fate of CDM with Z2 sym

- Spontaneously broken local U(1)x can do the job to some extent, but there is still a problem

Let us assume a local $U(1)_X$ is spontaneously broken by $\langle \phi_X \rangle \neq 0$ with

$$Q_X(\phi_X) = Q_X(X) = 1$$

Then, there are two types of dangerous operators:

$$\phi_X^\dagger X H^\dagger H, \quad \text{and} \quad \phi_X^\dagger X O_{\text{SM}}^{(dim-4)}$$

Problematic !   Perfectly fine !

- These arguments will apply to all the CDM models based on ad hoc Z_2 symmetry

- One way out is to implement Z_2 symmetry as local U(1) symmetry (arXiv:1407.6588 with Seungwon Baek and Wan-Il Park)

- See a paper by Ko and Tang on local Z_3 scalar DM, and another by Ko, Omura and Yu on inert 2HDM with local $U(1)_H$

$$Q_X(\phi) = 2, \quad Q_X(X) = 1$$

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + -\frac{1}{4}X_{\mu\nu}X^{\mu\nu} - \frac{1}{2}\epsilon X_{\mu\nu}B^{\mu\nu} + D_\mu\phi_X^\dagger D^\mu\phi_X - \frac{\lambda_X}{4}\left(\phi_X^\dagger\phi_X - v_\phi^2\right)^2 + D_\mu X^\dagger D^\mu X - m_X^2 X^\dagger X$$

$$- \frac{\lambda_X}{4}\left(X^\dagger X\right)^2 - \left(\mu X^2\phi^\dagger + H.c.\right) - \frac{\lambda_{XH}}{4}X^\dagger X H^\dagger H - \frac{\lambda_{\phi_X H}}{4}\phi_X^\dagger\phi_X H^\dagger H - \frac{\lambda_{XH}}{4}X^\dagger X \phi_X^\dagger\phi_X$$

The lagrangian is invariant under $X \to -X$ even after $U(1)_X$ symmetry breaking.

Unbroken Local Z2 symmetry

$$X_R \to X_I \gamma_h^* \quad \text{followed by} \quad \gamma_h^* \to \gamma \to e^+ e^- \quad \textbf{etc.}$$

The heavier state decays into the lighter state

The local Z2 model is not that simple as the usual Z2 scalar DM model (also for the fermion CDM)
