DQC

CMB temperature fluctuations reflect density fluctuations and small/large scale structure:

イロト イヨト イヨト

Ξ

The problem

Probe scalar in the Poincare patch of (rigid) de Sitter space (H = const):

$$\varphi, V(\varphi)$$
 $ds^2 = a^2(\tau)(-dt^2 + dx^2), a = (H\tau)^{-1}.$

Wavelengths stretch $\lambda = \ell a$, wavevectors shrink p = k/a.

 * Q: What is the statistics (correlators/PDF) of long modes? (random process in an open system)

* Methods: QFT (Feynman graphs) = Stochastic (Langevin eq)

 $\mathcal{V}(arphi)$ on dS

$$S = \int d^3x d\tau \ a^2 \left[\frac{1}{2} \dot{\varphi}^2 - \frac{(\nabla \varphi)^2}{2} - a^2 \mathcal{V}(\varphi) \right]$$
$$\mathcal{V}(\varphi) = \sum_{n=2}^{\infty} \frac{\lambda_n^{\text{bare}}}{n!} \varphi^n$$

We will be interested in single-point statistics (i.e. histograms marginalised over x)

$$\langle \varphi^n \rangle = \langle \varphi(\mathbf{x}_1) \cdots \varphi(\mathbf{x}_n) \rangle \Big|_{\mathbf{x}_1 = \cdots = \mathbf{x}_n} \propto \lambda_n^{\text{obs}}$$

i

< 三 → < 三 → ...

Spyros Sypsas Chulalongkorn U., Thailand Stochastic dynamics from QFT

UV/IR structure of correlators

The simplest correlator is the (free theory) one-point variance:

$$\sigma^2 = H^2 \int_0^\infty \frac{\mathrm{d}\mathbf{k}}{(2\pi)^3} \frac{1}{k^3} \left(1 + (k\tau)^2\right)$$

or, in physical momentum $p \equiv H k \tau$

$$\sigma^{2} = \left(\frac{H}{2\pi}\right)^{2} \int_{0}^{\infty} \frac{\mathrm{d}p}{p} \left(1 + \frac{p^{2}}{H^{2}}\right)$$

UV divergence: $\propto p^2$ IR divergence: $\propto \ln p$

Cure for external legs: restrict to long modes

Long-mode statistics

Long-short split: $\varphi = \varphi_S + \varphi_L$:

$$arphi_L(x,t) \equiv \hat{L} \{ \varphi(x,t) \} = \int_k e^{ikx} W(k) \tilde{\varphi}_k(t)$$

 $W(k) = \theta(k_*(t) - k) \times \theta(k - k_*(t_i)) \mid\mid W(p) = \theta(H - p) \times \theta(p - k_*(t_i)/a)$

Cut off external legs at $k_*(t_{
m i})\equiv k_{
m IR}.$ This is our choice!

Spyros Sypsas Chulalongkorn U., Thailand Stochastic dynamics from QFT

Now

$$\sigma_L^2(t) = \left(\frac{H}{2\pi}\right)^2 \int_{H/a}^H \frac{\mathrm{d}p}{p} = \frac{H^3 t}{4\pi^2}$$

We regularized but we now have a secular behaviour.

Linear modes independent \rightarrow variance additive \rightarrow blows up asymptotically (secular).

Cure: resummation (e.g. stochastic formalism)

Daisy loops

Do loops change the secular growth?

$$\mathcal{V}(arphi) = \lambda_4^{\mathrm{bare}} arphi^4 + \lambda_6^{\mathrm{bare}} arphi^6 + \cdots, \quad (ext{e.g. axion } \mathcal{V} \propto 1 - \cos arphi/f)$$

Recall that loops are virtual processes; they control the validity.

Cure for internal legs: UV & IR cutoffs or dim reg + renormalization

Now there is a choice to be made! Comoving vs physical IR cutoff.

Is t_i part of the theory?

Let us choose a physical cutoff. Then

$$\sigma_0^2 = \left(\frac{H}{2\pi}\right)^2 \int_{\Lambda_{\rm IR}}^{\Lambda_{\rm UV}} \frac{\mathrm{d}p}{p} = \left(\frac{H}{2\pi}\right)^2 \ln \frac{\Lambda_{\rm UV}}{\Lambda_{\rm IR}}$$

SK, in-in, WFU: n-pt functions loop-resummed to:

$$\left\langle \varphi^{n}(\tau) \right\rangle_{c} = -\frac{8\pi}{H^{4}} \operatorname{Im} \left\{ \int_{0}^{\infty} dx \int_{\tau_{i}}^{\tau} \frac{\tau^{2}}{\bar{\tau}^{4}} \lambda_{n}^{\operatorname{obs}} \left[g(x, \bar{\tau}, \tau) \right]^{n} \right\}$$

with g the propagator and

$$\lambda_n^{\rm obs} = \sum_{L=0} \frac{\lambda_{n+2L}^{\rm bare}}{L!} \left(\frac{\sigma_0^2}{2}\right)^L$$

(This is nothing but the coefficients of a Weierstrass transform)

The PDF of long modes

Edgeworth expansion of the PDF truncated to linear order in the interactions (single-vertex diagrams):

$$\rho(\varphi, t) = \frac{e^{-\frac{1}{2}\frac{\varphi^2}{\sigma^2(t)}}}{\sqrt{2\pi\sigma^2(t)}} \left[1 + \Delta(\varphi, t)\right]$$

with

$$\Delta(\varphi, t) = \sum_{n=0}^{\infty} \frac{1}{n!} \frac{\left\langle \varphi^{n}(t) \right\rangle_{c}}{\sigma^{n}} \operatorname{He}_{n}(\varphi/\sigma)$$

Perturbative QFT = Gaussian variables =

Upon using

$$\mathcal{O}_{\varphi}\mathrm{He}_{n}(\varphi/\sigma) = -n\mathrm{He}_{n}(\varphi/\sigma)$$

the PDF can be resummed:

$$\Delta(\varphi,\tau) = \frac{8\pi}{H^4} \operatorname{Im} \int_0^\infty dx \int_{\tau_i}^\tau \overline{\tau}^2 \left(\frac{g(x,\overline{\tau},\tau)}{\sigma^2}\right)^{-\mathcal{O}_{\varphi}} \underbrace{e^{-\frac{\sigma_0^2}{2}} \frac{\partial^2}{\partial \varphi^2} \mathcal{V}(\varphi)}_{\mathcal{V}_{\operatorname{ren}}(\varphi)}$$

such that $\rho = \rho_0 \left[1 + \Delta \right]$

This is the PDF of long modes

I = E = I

E

k au
ightarrow 0 limit:

$$\Delta(\varphi, t) = \frac{Ht}{3H^2} \left(\mathcal{V}_{\rm ren}''(\varphi) - \frac{\varphi}{\sigma^2} \mathcal{V}_{\rm ren}'(\varphi) \right)$$

and we then take a time derivative of the PDF:

$$\dot{
ho} = rac{H^3}{8\pi^2}rac{\partial^2}{\partialarphi^2} igg[
ho \Big(1 - rac{2Ht}{3H^2} \mathcal{V}_{
m ren}''\Big)igg] + rac{1}{3H}rac{\partial}{\partialarphi} \Big(
ho \mathcal{V}_{
m ren}^{'}\Big)$$

Fokker-Planck equation

글 네 글 네 글 네 크

E

Performing the same computation with a comoving IR cutoff:

$$\left\langle \varphi^{n}(t) \right\rangle_{c} = -\frac{4\pi^{2}n}{3H^{4}}\sigma^{2n}(t)\sum_{L}^{\infty}\frac{\lambda_{n+2L}}{(n+L)L!}\left(\frac{\sigma^{2}(t)}{2}\right)^{L}$$

leads to a PDF that satisfies the autonomous Fokker-Planck eq:

$$\dot{\rho} = \frac{H^3}{8\pi^2} \frac{\partial^2 \rho}{\partial \varphi^2} + \frac{1}{3H} \frac{\partial}{\partial \varphi} \left(\rho \mathcal{V}'_{\text{ren}} \right) \quad || \quad \left[\rho_{\infty} \propto e^{-\mathcal{V}/H^4} \right]$$

Starobinsky '86; Tsamis & Woodard '05; +++

- 同 ト - 三 ト - 三 ト

Physical cutoff: loops renormalise the vertex

Comoving cutoff: Loops enhance secular growth

The stochastic approach: Starobinski-Yokoyama 90's

How to model the effect of short modes at large scales? $\hat{\varphi}_k = \varphi_{\text{lin}} \hat{a}_k + \varphi^*_{\text{lin}} \hat{a}^{\dagger}_k \rightarrow \hat{\xi}_k = \varphi_{\text{lin}} (\hat{a}_k - \hat{a}^{\dagger}_k)$ The EOM for long modes now becomes a stochastic Langevin equation: for $\Delta t \gg 1/H$,

$$\dot{arphi}_L = H\hat{\xi}(t) - rac{1}{3H} \mathcal{V}_{
m ren}'(arphi_L)$$

where $\hat{\xi}(t)$ is a Gaussian stochastic noise representing the short-mode bath:

$$\hat{\xi} \equiv \mathcal{H}^{-1} \int_{k} \dot{\mathcal{W}}(k) \, ilde{arphi}_{k} \,, \quad \left\langle \hat{\xi}(t_{1}) \hat{\xi}(t_{2})
ight
angle \propto \delta(t_{1}-t_{2})$$

From this one can straightforwardly get the autonomous FP equation: integrate Langevin

$$\varphi_L(t) = \varphi_G(t) - \frac{1}{3H} \int \mathrm{d}t' \, \mathcal{V}'_{\mathrm{ren}} \left[\varphi_G(t') \right]$$

compute

$$\langle \varphi_L^n(t) \rangle_c$$

plug in Edgeworth and derive:

$$\dot{\rho} = \frac{H^3}{8\pi^2} \frac{\partial^2 \rho}{\partial \varphi^2} + \frac{1}{3H} \frac{\partial}{\partial \varphi} \left(\rho \mathcal{V}_{\text{ren}}' \right)$$

Stochastic dynamics from QFT

Langevin from in-in

 $\varphi(x, t) = U(t)\varphi_I(x, t)U^{\dagger}(t)$, where $\varphi_I(x, t)$ is the interaction-picture field and $U = \exp \left\{ -i \int dt' \int d^3x' \mathcal{V}_{ren}(\varphi_I) \right\}$.

To first order in the potential:

$$arphi(t) \simeq arphi_l(t) - rac{1}{3H} \int \mathrm{d}t' \, \mathcal{V}_{\mathrm{ren}}' \left[arphi_l(t')
ight]$$

Now apply \hat{L} :

$$\varphi_L(t) \simeq \varphi_G(t) - \frac{1}{3H} \int \mathrm{d}t' \, \hat{L} \left\{ \mathcal{V}_{\mathrm{ren}}' \left[\varphi_I(t') \right] \right\}$$

Computing

 $\langle \varphi_L^n(t) \rangle_c,$

and following the same steps now leads to

$$\dot{\rho} = \frac{H^3}{8\pi^2} \frac{\partial^2}{\partial \varphi^2} \left[\rho \left(1 - \frac{2Ht}{3H^2} \mathcal{V}_{\rm ren}'' \right) \right] + \frac{1}{3H} \frac{\partial}{\partial \varphi} \left(\rho \mathcal{V}_{\rm ren}' \right)$$

Spyros Sypsas Chulalongkorn U., Thailand

Stochastic dynamics from QFT

The choice that was made is

$$\hat{\boldsymbol{L}}\left\{\mathcal{V}_{\mathrm{ren}}'\left[\varphi_{\boldsymbol{l}}(\boldsymbol{t}')\right]\right\}=\mathcal{V}_{\mathrm{ren}}'(\hat{\boldsymbol{L}}\varphi_{\boldsymbol{l}})$$

When does this hold? When we negelct short-long mode correlations. (equivalent to comoving vs physical loop cutoffs)

Separate the IR modes

 $\varphi = \varphi_{\mathbf{S}} + \varphi_{\mathbf{L}} + \varphi_{\mathrm{IR}}$

and integrate them out:

$$\mathcal{V}(ar{arphi}) = \langle \Psi_{\mathrm{IR}} | \mathcal{V}(ar{arphi} + arphi_{\mathrm{IR}}) | \Psi_{\mathrm{IR}}
angle$$

with

$$|\Psi_{
m IR}
angle = \int {\cal D}arphi_{
m IR} \Psi(arphi_{
m IR}) |arphi_{
m IR}
angle$$

with $|\varphi_{\rm IR}\rangle$ an IR field-eigenstate and $|\Psi(\varphi_{\rm IR})|^2$ the Gaussian. This leads directly to

$$\mathcal{V}(ar{arphi})=\mathcal{V}_{ ext{ren}}(ar{arphi})$$
